

Video Preparation Software for Segmenting, Trimming, and Proxy Editing

NPoint is an ideal solution for preparing multi-segmented video clips in your file server for commercial insertion, trimming, previewing, or editing. This highly efficient application enables you to view video from any standard broadcast device, such as a video server or tape machine, or by playing a low-res proxy of the clip from any video player.

Once material resides on a server or a proxy has been created, the file can easily be previewed and edited using NPoint, giving you a long list of options for segmenting and trimming as you shuttle through the clip.

Conveniently, no change is made to the video itself. Instead, the NBase media database manager retains all your desired start and end points and stores them in the SQL database — and all this information is instantly available to other applications on the network.

The NPoint application is perfect for preparing multi-segmented video clips for inserting commercial content as well as trimming and previewing video. The easy to use system can be controlled using the keyboard, the intuitive GUI or an optional job/shuttle knob.

Benefits:

- Adaptable to any workflow due to configurable functionality and appearance
- Saves time and money with multiple functions in a single application
- High performance video file preparation

Features:

- Trim or segment an video file
- Create virtual or sub-clips
- Maintain a list of segmented clips with duration, start, and end points
- On-screen or keyboard job/shuttle controls
- Easy-to-use editing tools and low-res proxies
- Trim clips and create database sub-clips
